

## **Care of Sealants**

By forming a thin covering over the pits and fissures, sealants keep out plaque and food, thus decreasing the risk of decay. Since, the covering is only over the biting surface of the tooth, areas on the side and between teeth cannot be coated with the sealant. Good oral hygiene and nutrition are still very important in preventing decay next to these sealants or in areas unable to be covered.

Your child should refrain from eating ice or hard candy, which tend to fracture the sealant. Regular dental appointments are recommended in order for your child's dentist to be certain the sealants remain in place.

The American Dental Association and the American Academy of Pediatric Dentistry recognize that sealants can play an important role in the prevention of tooth decay. When properly applied and maintained, they can successfully protect the chewing surfaces of your child's teeth. A total prevention program includes regular visits to the dentist, the use of fluoride, daily brushing and flossing, and limiting the number of times sugar-rich foods are eaten. If these measures are followed and sealants are used on the child's teeth, the risk of decay can be reduced or may even be eliminated!

As a service to our patients, if your sealants were done by our office and you come for your regular 6 month re-care appointments, we will gladly replace any sealants that may fall off within the first year of placement.
